Christopher L. Barrett

January 2000

## LOS ALAMOS NATIONAL LABORATORY

Los Alamos National Laboratory, an affirmative action/equal opportunity employer, is operated by the University of California for the U.S. Department of Energy under contract W-7405-ENG-36. By acceptance of this article, the publisher recognizes that the U.S. Government retains a non-exclusive, royalty-free license to publish or reproduce the published form of this contribution, or to allow others to do so, for U.S. Government purposes. Los Alamos National Laboratory requests that the publisher identify this article as work performed under the auspices of the U.S. Department of Energy. The Los Alamos National Laboratory strongly supports academic freedom and a researcher's right to publish; as an institution, however, the Laboratory does not endorse this viewpoint of a publication or guarantee its technical correctness.

# Estimating Accidents Using TRANSIMS

Suhan Ree, Iisakki Kosonen,  
Stephen Eubank, and Christopher L. Barrett

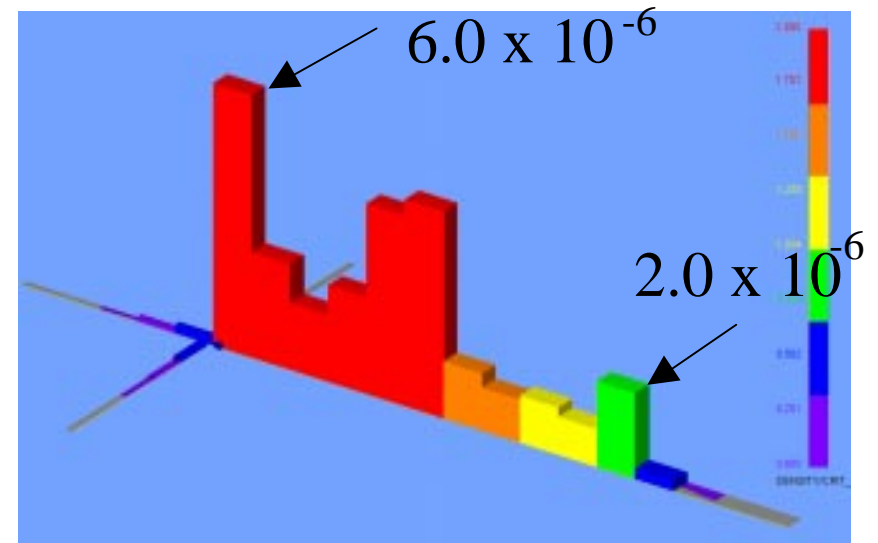

TSA-SA, Los Alamos National Laboratory

# Our Goal

- Fact : TRANSIMS is collision-free.
- Intuition : Use the rare hard decelerations that occur to avoid collisions to estimate probability distributions of accidents in time and space.
- Goal
  - ♦ Estimate likelihood of accidents in a given network using TRANSIMS.
  - ♦ Reduce data requirements as much as possible.

# Interpretation of our results

- Method provides relative likelihood of accidents distributed in a whole network and in time.

- ♦ Results can be used as relative safety measures in a network.
- ♦ Regional accident field data can be used to give a scaling constant to estimate the likelihood of accidents.

# Basic Approach

- If a vehicle cannot "decelerate" enough, there will be a collision.
  - Types of multi-vehicle accidents depicted:
    - ◆ rear-end
    - ◆ lane-changing
    - ◆ intersection or junction
- 61 % of all accidents, and 89 % of all multi-vehicle accidents

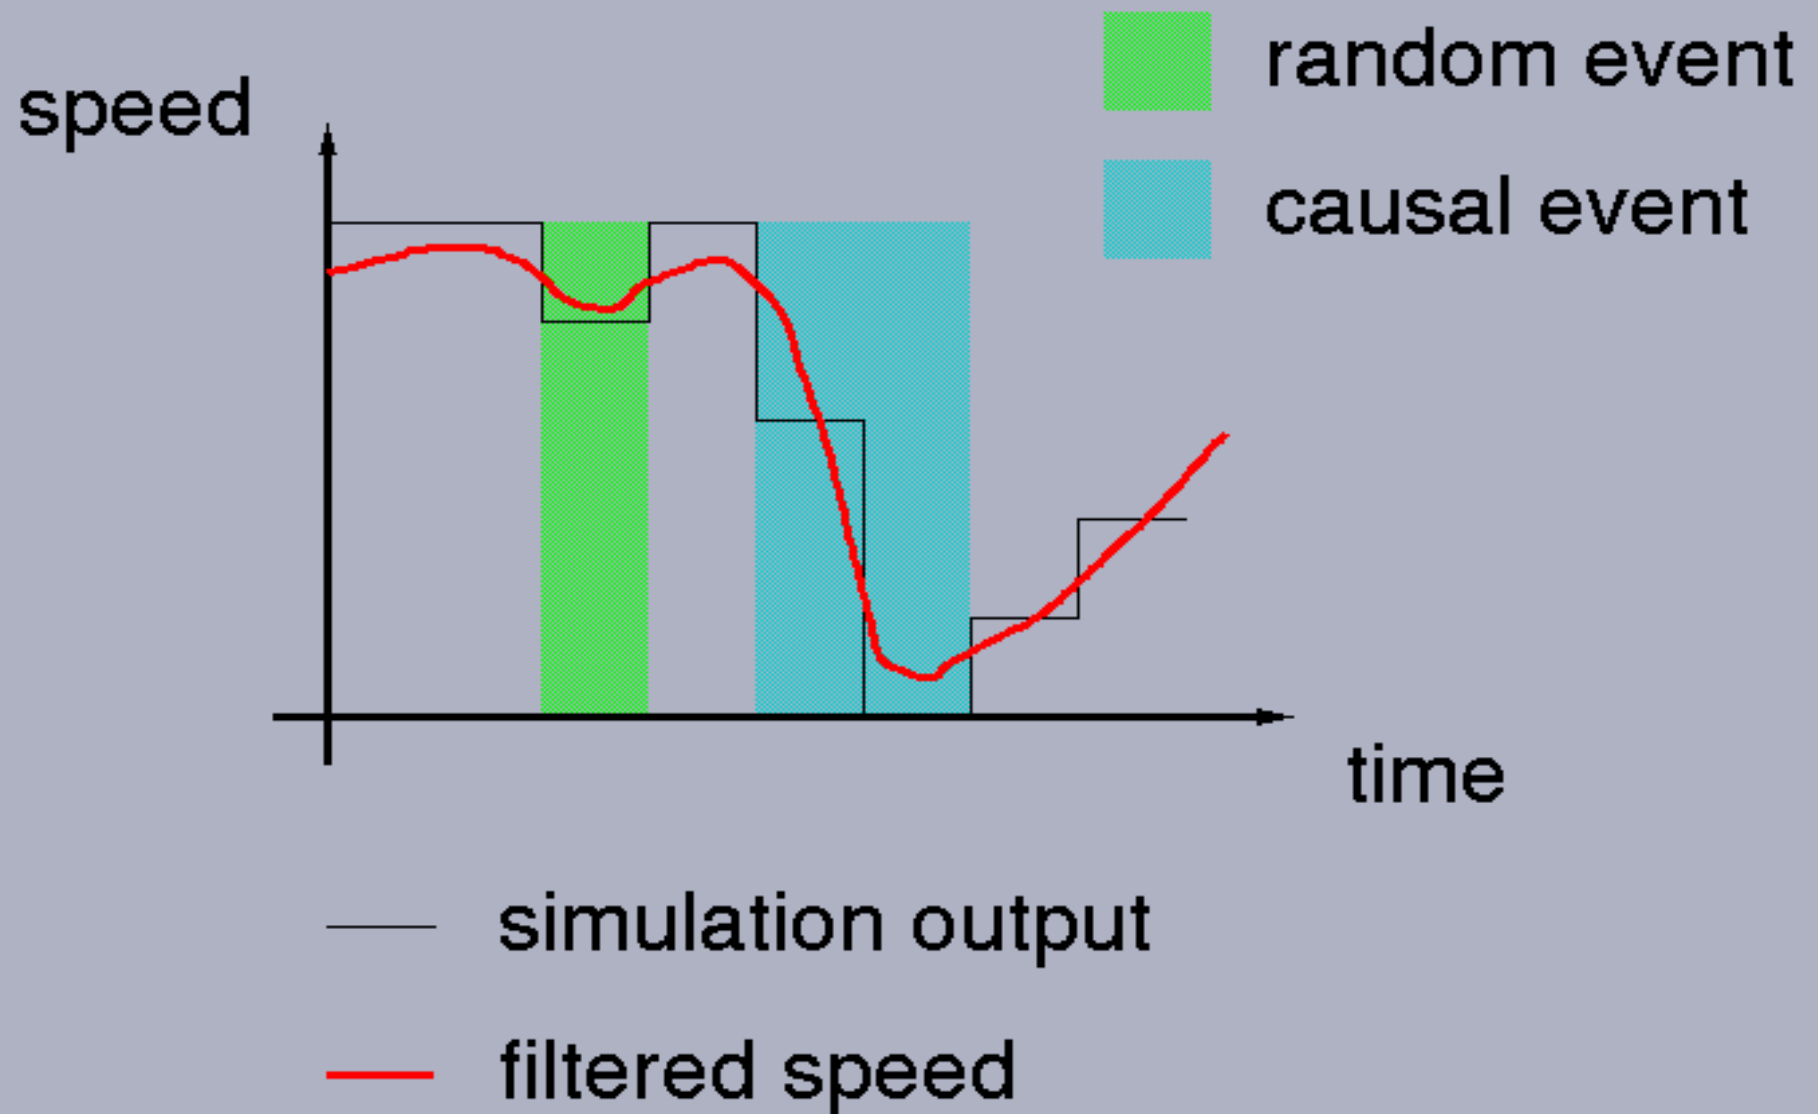

# Overview of Our Procedure

- 1 Find all "deceleration events."
- 2 Categorize them by type and by braking power ( $V \cdot D$ ).
- 3 Assign the probability of an accident for each deceleration event.
- 4 Calculate the expected number of accidents in a given location and a given time interval.

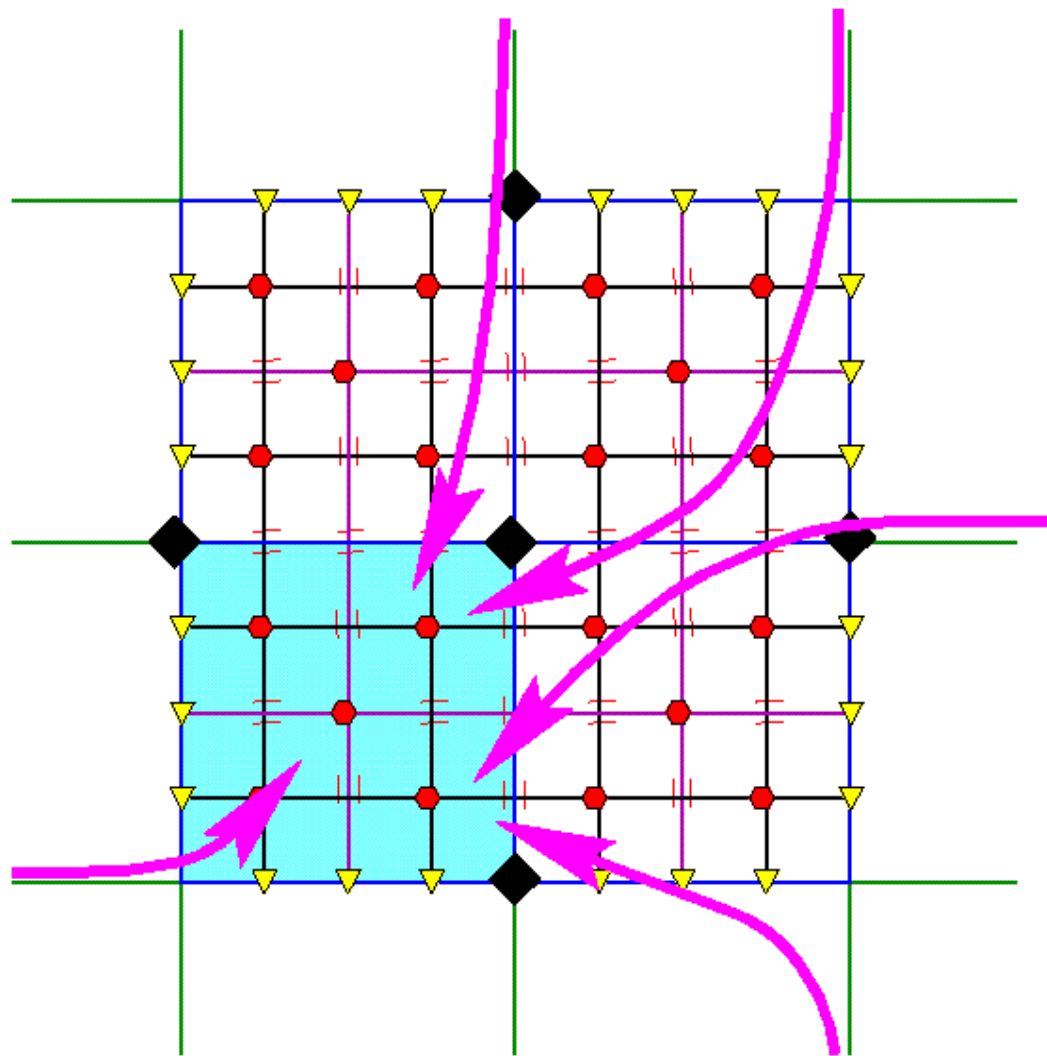

# When Vehicles Decelerate in TRANSIMS

- 1 Random deceleration
- 2 Causal deceleration
  - a when the gap is too small
    - during forward movements
    - when trying to change lanes
  - b traffic control

# Definition of Deceleration Events

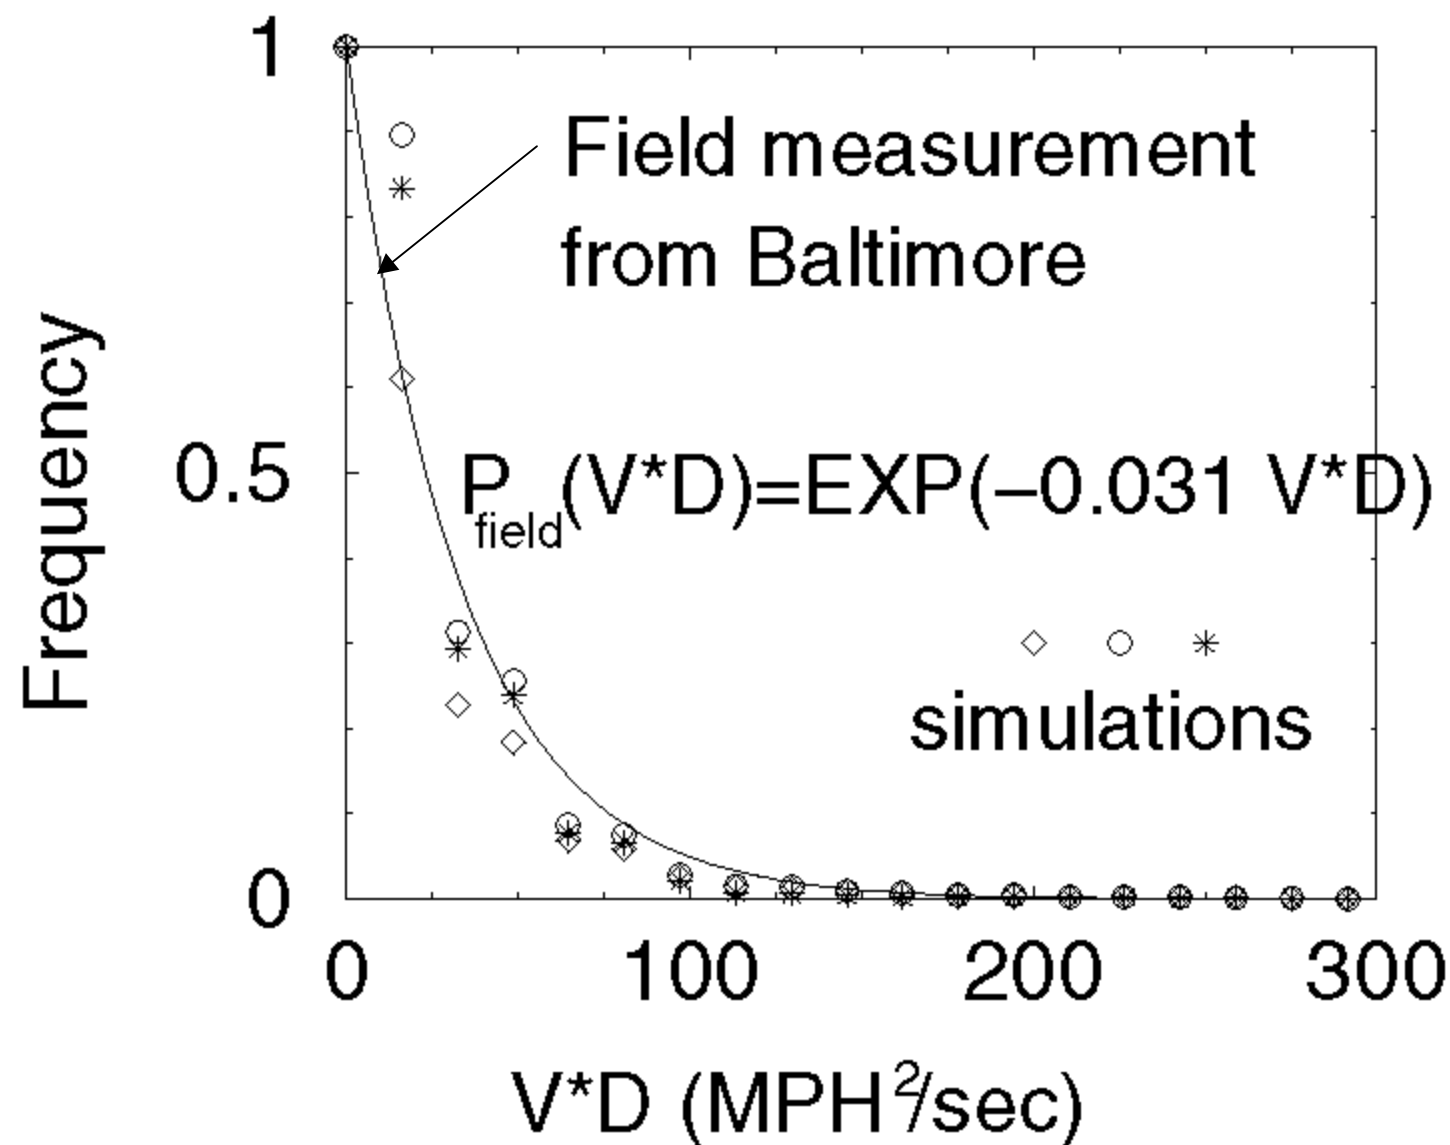

## A Calibration Network and a Scenario

◆ , ● , ▼ , =  
various kinds  
of traffic controls

— , — , — , —  
various kinds  
of roads

# CUMULATIVE DISTRIBUTION

# Probability of Accident

- In extreme deceleration events, the probability of accident depends only on the braking power.

- Our postulate

(probability of an accident)

$\propto$  (prob. of not being able to decelerate)

$\propto (1 - P_{Field}(V * D))$

Prob. of Accident

**feasible**

$$C[1 - P_{\text{field}}(V^*D)]$$

cut-off

200

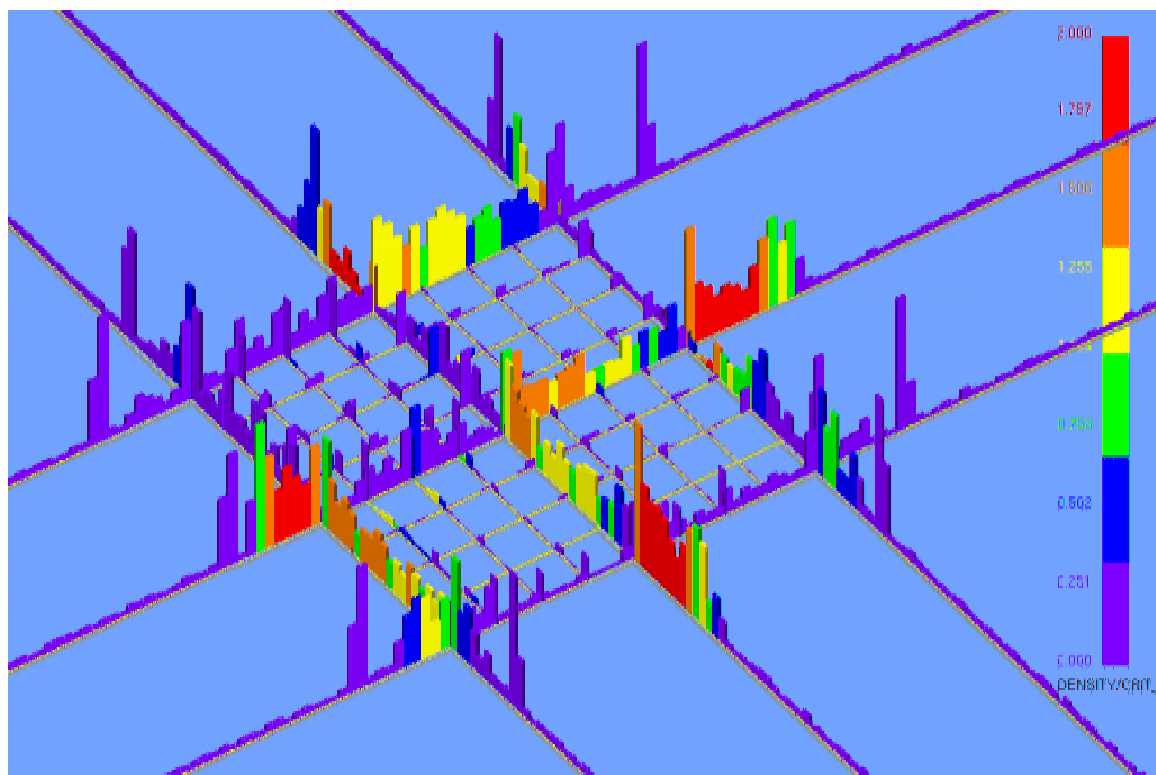

300

$V^*D$  (MPH<sup>2</sup>/sec)

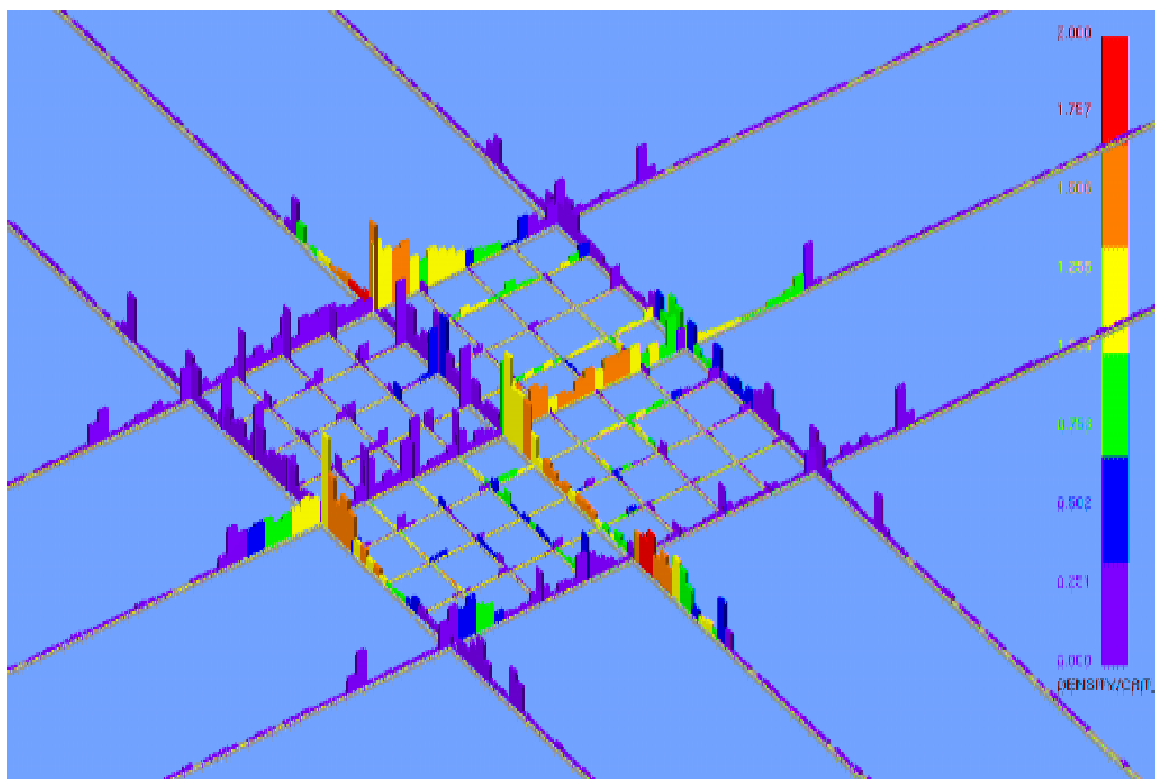

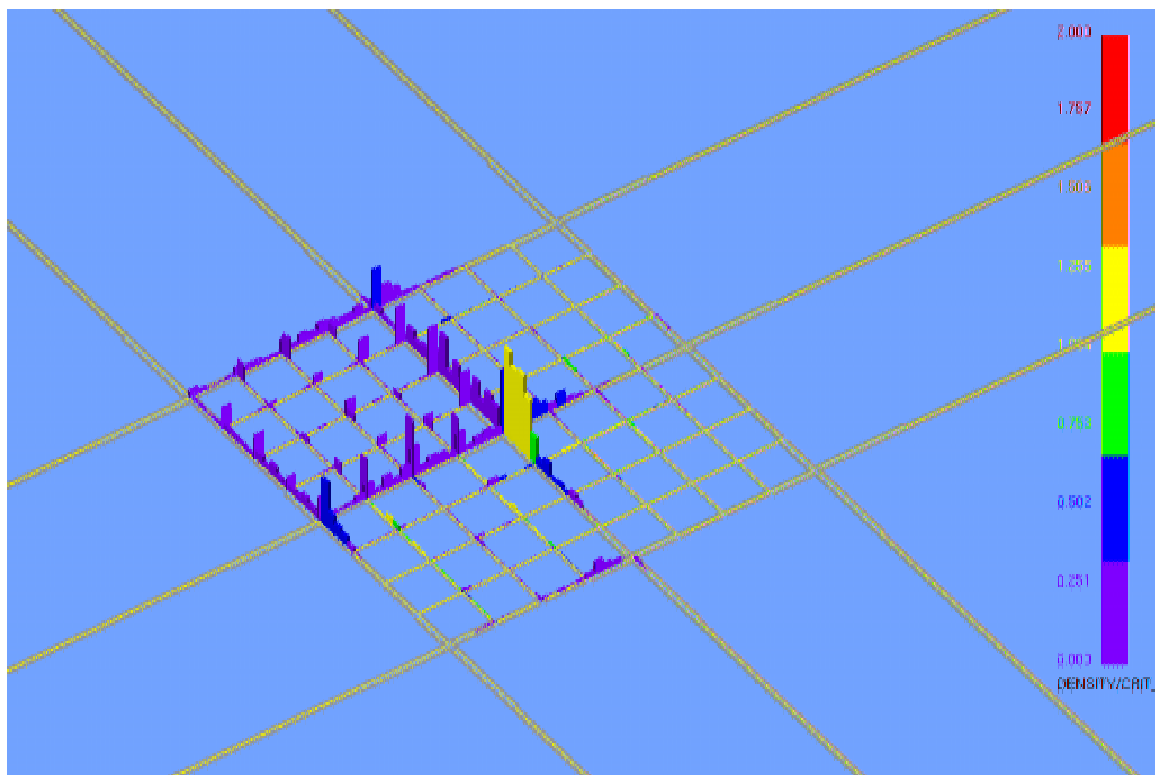

1-15 minutes

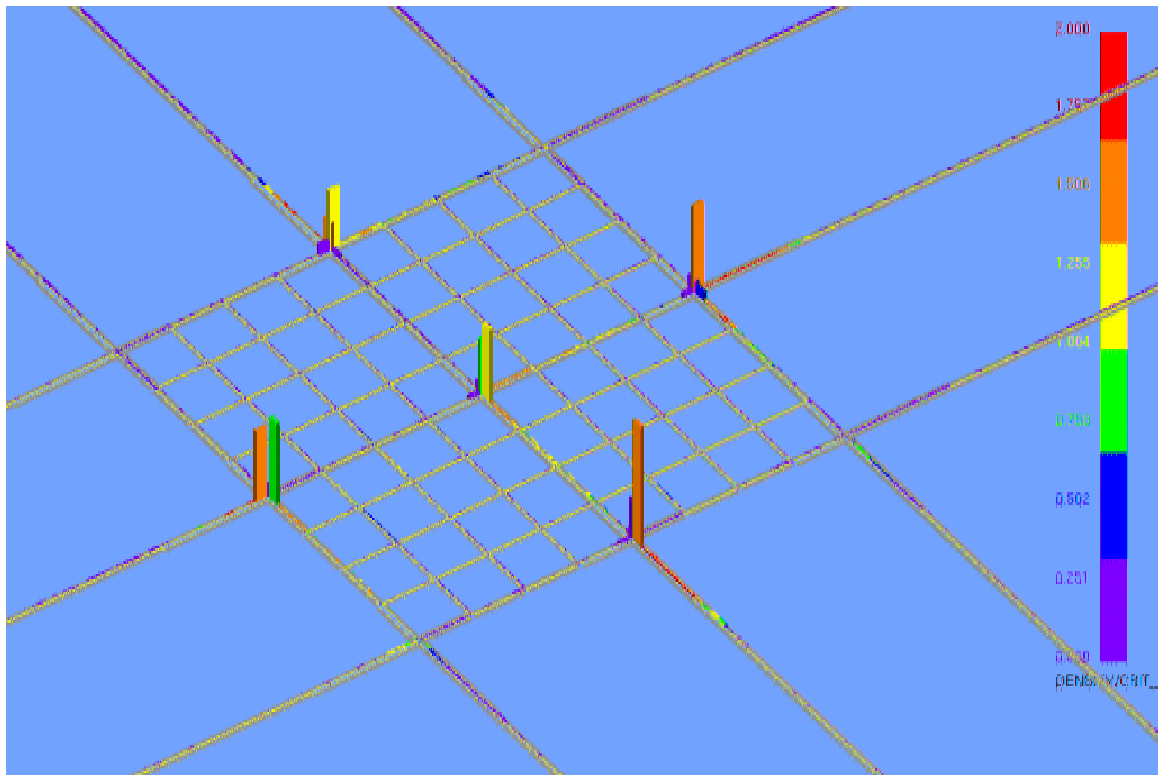

16-30 minutes

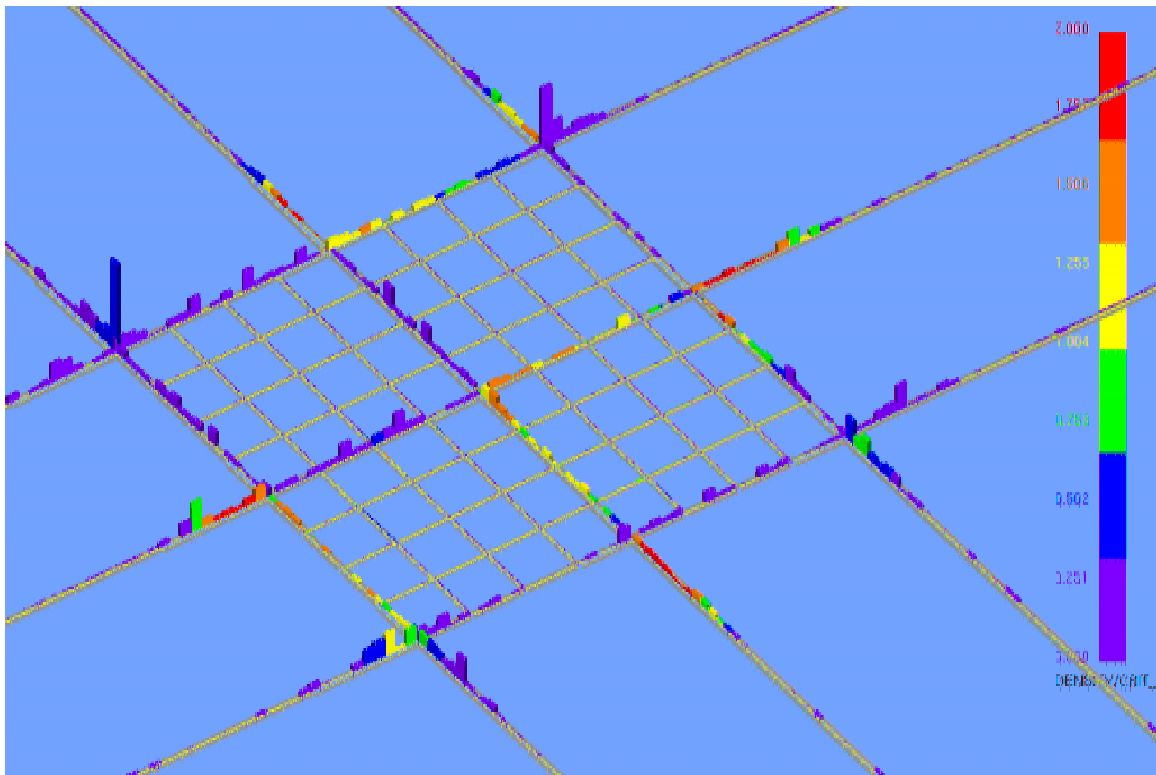

31-45 minutes

46-60 minutes

Intersection (signalized) accidents

Lane-changing accidents

# Conclusions

- Our method using TRANSIMS outputs generates verifiable accident likelihood by time, by link, and by type.
- Field data shows good match of simulated deceleration behaviors to measured.
- The method can be elaborated and tuned.
